Results

• Of the 607 SV infants included, 44 (7.2%) met the primary outcome.

• Univariate Analysis: Non-Hispanic/Non-Latino patients, patients with predischarge ventricular dysfunction, post-op renal failure, or post-op AVVR were more likely to experience the primary outcome (Table 3). Rate of reaching outcome did not correlate with SES tertile (Table 3).

• Multivariable Analysis: Even after multivariable adjustment for potentially confounding factors, SES was not associated with death/needing

 The odds of reaching the outcome were no different for those in the middle or upper tertile when compared to the lowest (Figure 1).

Conclusion

• In this large cohort of SV infants enrolled in a digital remote monitoring program during the ISP, we found no difference in outcomes based upon

• These findings differ from prior studies showing worse outcomes for SV

• Our study suggests this novel technology could help mitigate differences in outcomes for this fragile population of patients.
